

To conclude, Dr Fink noted that another study [Macbeth et al. ASH 2014 (abstr 3606)] showed similar results regarding lenalidomide inducing ubiquitination of CSNK1A1 by the CRBN-CRL4 and its subsequent degradation.

## Th17-Prone CD146<sup>+</sup>CCR5<sup>+</sup> T-Cell Population Is an Early Marker of Intestinal GVHD

Written by Maria Vinal

Acute graft-vs-host disease (GVHD) is a major complication of allogeneic hematopoietic stem cell transplantation (HSCT), primarily affecting the skin, liver, and gastrointestinal (GI) tract. GVHD limits the role of transplantation in other clinical settings, such as the treatment of severe autoimmune disorders. T lymphocytes in the peripheral blood play a central role in immunity and in the process whereby newly transplanted donor cells attack the transplant recipient's body.

In a late-breaking clinical trial [Li W et al. *Blood*. 2014], Wei Li, MD, PhD, Indiana University, Indianapolis, Indiana, USA, reported that early quantification of a novel Th17-prone CD146<sup>+</sup>CCR5<sup>+</sup> inducible T-cell costimulator (ICOS)-induced population may identify patients at risk for GI GVHD development and subsequent mortality.

Peripheral blood cells from 214 HSCT patients (71 GI GVHD, 48 no GVHD, 33 non-GVHD enteritis, 22 skin-first GVHD, 40 isolated-skin GVHD) were analyzed using proteomics 14 days prior to the onset of GVHD symptoms. Biomarkers that increased 1.5-fold were identified in the plasma from GI GVHD patients and compared with HSCT patients without GVHD at matched time points. Two proteins were identified: CD146, a cell adhesion and trafficking molecule expressed on a subset of CD4<sup>+</sup> T cells and endothelial cells, and the chemokine (C-C motif) ligand 14, which binds to the chemokine receptor CCR5 on T cells.

CD146<sup>+</sup>CCR5<sup>+</sup> T-cell frequency was significantly increased in patients with GI GVHD compared with patients without GVHD ( $P < .0001$ ), non-GVHD enteritis ( $P < .0001$ ), or isolated-skin GVHD ( $P = .007$ ) but not with skin-first and then GI GVHD ( $P = .28$ ).

CD146<sup>+</sup>CCR5<sup>+</sup> T cells were not correlated with GI histologic severity and increased prior to GVHD clinical onset. CD146<sup>+</sup>CCR5<sup>+</sup> T cells were Th17 prone in that Th17 cells express more CD146 than Th1 cells. The activation marker ICOS, known to be critical for the

development of human Th17 cells, was also critical for the expression of CD146<sup>+</sup>CCR5<sup>+</sup> on T cells.

Th17 cells migrated more efficiently through endothelial-cell monolayers than their Th1 counterparts, suggesting that endothelium may play an important role in recruiting pathogenic T cells. This was supported by evidence showing that CD146 Th17 transmigration is reduced by CD146 shRNA knockdown on T cells. However, knockdown of CD146 on endothelial cells does not reduce T-cell transmigration.

Finally, to evaluate the in vivo function of CD146 T cells, donor human T cells knockdown with CD146shRNA were transmigrated into a xenogeneic GVHD mouse model. Mice did not lose weight, had similar human T-cell engraftment (hCD4), had fewer splenic CD146<sup>+</sup>CCR5<sup>+</sup>T cells, and expressed less interferon gamma 53 days after transplant, providing proof that CD146 promotes infiltration of pathogenic T cells into GVHD target organs.

The CD146<sup>+</sup>CCR5<sup>+</sup> cell population is a biomarker of GI GVHD. Early quantification of this population of cells may predict the development of GI GVHD and offer more specific prevention and therapeutic strategies, thereby reducing mortality.

## Sorafenib as Effective Treatment for Newly Diagnosed AML in Younger Patients

Written by Maria Vinal

Christoph Röhlig, MD, Universitätsklinikum Dresden, Dresden, Germany, presented the results of the Study Evaluating Sorafenib Added to Standard Primary Therapy in Patients With Newly Diagnosed Acute Myeloid Leukemia Less Than 60 Years of Age [SORAML; Röhlig C et al. ASH 2014 (abstr 6)]. Although overall survival (OS) was not different compared with placebo, sorafenib significantly improved event-free survival (EFS) and relapse-free survival (RFS) with a cost of higher incidence of infections and bleeding events in younger patients with acute myeloid leukemia (AML).

AML is the most common form of leukemia in adults [National Cancer Institute. <http://www.cancer.gov/cancer-topics/pdq/treatment/adultAML/Patient/page1>. Accessed December 23, 2014]. Survival rate for this disease continues to remain unsatisfactory, particularly among patients aged >60 years. The significant genetic diversity and abnormality in AML even within a tumor of a single individual make it difficult to treat [Cancer Genome Atlas Research Network. *N Engl J Med*. 2013]. Kinase mutations
